GAS TAP WITH AN ELECTROMAGNETIC SAFETY VALVE AND  
MAGNETIC INSERT FOR AN ELECTROMAGNETIC SAFETY VALVE

The present invention relates to a gas tap with an electromagnetic safety valve and a magnetic insert for an electromagnetic safety valve for inserting in the gas tap, which magnetic insert has a mobile armature in an armature housing arranged with a valve closing element and an electromagnetic coil. To close a gas path provided in the gas tap the magnetic anchor presses the valve-closing element onto a valve seat provided in the gas tap. When voltage is applied to the electromagnetic coil the magnetic anchor is actuated.

DE 1 959 057 discloses a generic magnetic insert in particular for monitoring devices on gas-heated units. The magnetic insert has an electromagnet mounted on a bearing plate and an armature plate, which is connected to a valve tappet. The valve tappet is displaceably mounted in a protective capsule enclosing the electromagnet and the armature plate. Attached to the end of the valve tappet opposite to the armature plate is the closing member of a shut-off valve. Comparable magnetic inserts are also known from EP 1 036 987 and EP 1 063 474.

The object of the present invention is to provide a gas tap with an electromagnetic safety valve or respectively a magnetic insert for the electromagnetic safety valve, whereof the service life is prolonged.

The task of the invention is solved by a gas tap having the features of Claim 1 as well as a magnetic insert having the features of Claim 13. According to the characterising parts of Claim 1 or respectively Claim 13 the electromagnetic coil is arranged as a separate component outside the armature housing of the magnetic

insert. Due to the external arrangement of the electromagnetic coil mechanical shock loads are no longer transferred directly from the magnetic anchor in the armature housing to the electromagnetic coil. The effect of such mechanical shock loads in known magnetic inserts with electromagnetic coils arranged inside the armature housing is that already after approximately 40,000 switching cycles electrical terminals of the electromagnetic coil tear. According to the present invention the number of switching cycles of the magnetic insert is clearly increased.

According to a particularly advantageous embodiment the electromagnetic coil can easily be disassembled on the magnetic insert and/or arranged gastight separately from the gas path in the gas tap. The electromagnetic coil can thus be exchanged problem-free as a wear-and-tear component, without gastight surfaces between the magnetic insert and the gas tap being damaged.

It is preferred if the electromagnetic coil is arranged outside the gas tap when the magnetic insert is inserted in the gas tap. This means that the electromagnetic coil can be exchanged without having to detach the magnetic insert from the gas tap.

The magnetic anchor of the magnetic insert can be extended beneficially to outside the gas tap. The extended magnetic anchor can be guided and moved more precisely in the armature housing and lower in clearance and/or friction. The wear on magnetic anchor guide sections in the armature housing is thereby reduced.

According to the type of two-point mounting the armature housing can have at least two magnetic anchor guide sections axially distanced from one another for

guiding the magnetic anchor. This effectively further improves the precise and low-friction motion of the armature. It is particularly advantageous for good control of the magnetic anchor if both guide sections are made of different materials, metal and plastic in particular.

It is preferred for good adjustment movement of the magnetic anchor if the distance between both guide sections is as great as possible. This can be done according to the present invention if a first magnetic anchor guide section of the armature housing is provided inside the gas tap, and a second magnetic anchor guide section of the armature housing is formed outside the gas tap. The number of switching cycles of the magnetic insert can be increased to more than 100,000 in particular in combination with the abovementioned features.

A fixed counter-anchor can be arranged preferably in the armature housing to boost a magnetic force of the magnetic insert. The counter-anchor also serves to limit an armature stroke.

In process engineering terms it is preferred if the armature housing is made in two parts from a first armature housing section set in the gas tap and a second armature housing section projecting from the gas tap. This means that the second armature housing section is preferably connected gastight with the gas tap.

In process engineering terms it is particularly preferred if the first armature housing section of the magnetic insert arranged in the gas tap is structurally identical to corresponding housing sections of commercially available magnetic inserts. In this case

the inventive magnetic insert can be used in existing mass-produced gas taps, without any retrofitting of the gas taps.

All modifications of the inventive magnetic insert are provided, by comparison, on the second armature housing section outside the gas tap.

Two embodiments of the invention are described hereinbelow by means of the attached figures, in which:

Figure 1 is a perspective view of a gas tap with an electromagnetic safety valve according to the first embodiment;

Figure 2 is a sectional view of the gas tap of Figure 1 along a plane through the lines I and II of Figure 1;

Figure 3 is a sectional view of the gas tap of Figure 1 along a plane through the lines I and III of Figure 1; and

Figure 4 is a sectional view of a gas tap corresponding to Figure 3 according to the second embodiment.

Figure 1 illustrates a conventional gas tap with a gas tap body 1. In the gas tap body 1 a tap axle 3 is pivotably mounted. A rotating knob, not illustrated, for actuating the gas tap is arranged on the upper free end of the tap axle 3. A gas inlet 5 of the gas tap body 1 can be connected to a gas supply, not illustrated. The gas inlet 5 is connected in terms of fluid technics via a gas path 6 evident in the following figures to a gas outlet 7. A gas flow in the gas path 6 runs along the arrows indicated in the figures. The gas tap shown in Figure 1 has a safety valve 8 with a magnetic insert 9. The magnetic insert 9

is screwed by means of a union nut 11 to the gas tap body 1.

According to Figure 2 a cock plug 13, swivel-mounted in a conical section of the gas tap body 1, is designed in the lower end of the tap axle 3. Depending on the rotational position of the cock plug 13 the passage of gas is adjusted by the gas path 6. The latter terminates in a frontal opening 14 on a horizontal Take-up bore 15 of the gas tap. The gas path 6 runs on through an opening in the cylindrical inner wall of the Take-up bore 15 to the gas outlet 7. In the Take-up bore 15 is set the magnetic insert 9. The magnetic insert 9 has an armature housing 19, in which a magnetic anchor 21 is guided. Formed on the magnetic anchor 21 is a transfer tappet 23. This protrudes against the direction of gas flow through a sleeve-like magnetic anchor guide section 25 of the armature housing 19. The free end of the transfer tappet 23 is formed as a spherical head 27. A valve head 29 with a seal 31 is attached thereon as a valve-closing element. The valve head 29 is somewhat movable relative to the spherical head 27 of the transfer tappet 23. Errors in angle between the magnetic insert 9 and the gas tap body 1 are thus compensated. A helical spring 33, which presses on the valve head 29, is supported on the armature housing 19. In Figure 2 the latter is pressed onto a valve seat 35 configured frontally in the Take-up bore 15, which encircles the frontal opening 14. As evident also from Figure 3, the gas path 6 between the gas inlet 5 and the gas outlet 7 is closed.

Figures 2 and 3 disclose that the armature housing 19 is made in two parts from a cost-effective plastic housing part 37 and an armature guide sleeve 39 of metal. The plastic housing part 37 is sunk fully in the Take-up bore 15 of the gas tap body 1. An open end of

the plastic housing part 37 lying opposite the sleeve-like guide section 25 is thrust onto an outer circumference of the armature guide sleeve 39. Here the plastic housing part 37 overlaps the armature guide sleeve 39 as far as a peripheral flange 41 of the armature guide sleeve 39. The peripheral flange 41 of the armature guide sleeve 39 is pressed gastight onto a frontal outer edge of the Take-up bore by means of the screwed-on union nut 43. The inner circumference of the armature guide sleeve 39 is in flat against the magnetic anchor 21. The inner circumference of the armature guide sleeve 39, as also the sleeve-like guide section 25, thus serves as a magnetic anchor guide section.

Mounted on the outer circumference of the armature guide sleeve 39 arranged outside the gas tap body 1 is an electromagnetic coil 45. To secure the electromagnetic coil 45 on the armature guide sleeve 39 a star wheel 47 is thrust onto the armature guide sleeve 39 at the front. The star wheel 47 is snaplocked in a peripheral groove of the armature guide sleeve 39. The electromagnetic coil 39 has electrical terminal contacts 49. These can be connected to an electrical fire-monitoring member, i.e. a thermoelement, or to an electronic control device for fully-automatic control of the safety valve 8. When there is a gas flame on a gas burner the thermoelement generates an electrical voltage, which is conveyed via the electric terminal contacts 49 to the electromagnetic coil 45 which it excites. A magnetic force is thereby applied to the magnetic anchor 21 against the spring force of the spring 33. The magnetic force brings the magnetic anchor 21 into an opened position, in which the valve head 29 is out of contact with the valve seat 35. If the flame should be extinguished during operation, the voltage and thus the

magnetic force break down. The magnetic anchor 21 is thus pressed against the valve seat 35 by means of the spring force of the spring 33. When the flame is extinguished the gas path 6 in the gas tap is thus closed. A counter-anchor 51 is arranged fixed in the armature guide sleeve 39 to increase the magnetic force of the electromagnetic coil 45 acting on the magnetic anchor 21. The counter-anchor 51 serves simultaneously to limit an opening stroke path of the magnetic anchor 21.

Figure 4 illustrates a magnetic insert 9 according to the second embodiment. Structure and function of the magnetic insert 9 are identical to the magnetic insert 9 of the first embodiment with the exception that a damping system for damping impacts of the magnetic anchor 21 on the counter-anchor 51 is additionally provided in the magnetic insert 9, as in Figure 4. The damping system has an O-ring 53 set into the outer circumference of the counter-anchor 51. The O-ring 53 is pressed in between the inner circumference of the armature guide sleeve 39 and the counter-anchor 51 and enables fixed mounting of the counter-anchor 51. At the same time the armature housing 19 is closed off gastight to the exterior. In addition, an attenuation disc 55 made of silicon material is added to damp the shocks exerted onto the counter-anchor 51 between the upper front side of the armature guide sleeve 39 and the counter-anchor 51. The upper front side of the armature guide sleeve 39 can, owing to the gastight seal via the O-ring 53, be designed with an opening 57 advantageous in process engineering terms, as shown in Figure 4.
